

# HIGFLY

HIGEE TO FURANIC-BASED  
JET-FUEL TECHNOLOGY

## Newsletter 4

This project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement N°101006618. The present publication reflects only the author's views and the European Union is not liable for any use that may be made of the information contained therein.

# THE HIGFLY PROJECT

As the **HIGFLY** project concludes on December 31, 2024, we proudly reflect on its transformative contributions to the development of **Sustainable Aviation Fuel (SAF)** technologies. Over the past four years, a consortium of nine partners, led by Eindhoven University of Technology, has worked to design cost-effective methods for converting **second-generation biomass** into SAF by designing state-of-the-art technologies, materials and chemo-catalytic processes.

HIGFLY focused on two primary pathways to maximise carbon efficiency and reduce environmental impacts:

## 1. C5 Sugar Conversion to Furfural

This pathway transformed lignocellulosic biomass into furfural through aldol condensation with acetone, producing SAF precursors. Subsequent hydrogenation and hydrodeoxygenation processes yielded hydrocarbons fit for aviation fuel, achieving an **88% carbon yield**—a significant step toward sustainable aviation solutions.

## 2. Cyclopentanone Pathway

Cyclopentanone, derived from furfural, underwent gas-phase condensation and hydrotreating to produce cyclic hydrocarbons. Operating at high temperatures with tailored catalysts, this pathway achieved near-complete hydrodeoxygenation, resulting in a hydrocarbon-rich product with minimal waste.

Central to these efforts was the **HiGee reactor**, an innovative technology developed to enhance furfural production. By employing high-gravity operations and advanced catalyst designs, the reactor has the potential to **increase furfural yield up to 90%** whilst

reducing energy consumption and reactor size significantly compared to conventional methods.

Fuel samples from both pathways are rigorously being tested by SkyNRG to ensure compliance with aviation standards, including critical properties like freezing point and flash point. These tests aim to validate HIGFLY's SAF as a viable alternative to fossil kerosene.

Beyond fuel production, the project explored advanced purification techniques using **deep eutectic solvents** and **supported liquid membranes**, enhancing extraction efficiency and overall sustainability. A comprehensive Life Cycle

Assessment demonstrated considerable greenhouse gas emission reductions, whilst the project's socio-economic analysis highlighted benefits such as rural job creation and economic growth.

HIGFLY's groundbreaking work advances the EU's climate goals and supports the aviation industry's transition toward a **net-zero future**. By unlocking the potential of renewable chemicals like furfural, HIGFLY has set the stage for sustainable innovations across aviation and related industries.

Keep reading to learn more about HIGFLY's potential impact on the future of sustainable aviation.

## Catalytic Condensation of Biobased Molecules for Jet Fuel Synthesis

This work evaluates a process for the production of renewable jet fuel hydrocarbons using biobased precursors derived from 2nd generation biomass hemicellulose. A set of promising basic solid formed catalysts was benchmarked in lab-scale continuous fixed bed reactors to evaluate their catalytic performance in the cross-condensation of furfural and acetone and the self-condensation of cyclopentanone at two different temperature regimes.

For the low temperature liquid process (80-120 °C), a hydrotalcite and a metal-organic-framework catalyst were most active and stable up to 53 h on stream, with high conversions (> 85 %) and favouring the formation of C13 over C8 products. For the high temperature gas-phase process (280-360 °C), a metal doped alumina catalyst was most active, with stable conversion (40-45 %) and a product distribution favouring C10 over C15 molecules.

The two process regimes (low and high temperature) can provide flexibility in the production of biobased hydrocarbons for use in the aviation sector. Catalyst deactivation was observed due to strong carbon adsorption; however, most active materials could be regenerated via calcination.

## Intensifying cyclopentanone synthesis from furfural using supported copper catalysts

This work addresses catalytic strategies to intensify the synthesis of cyclopentanone, a bio-based platform chemical and a potential SAF precursor, via Cu-catalyzed furfural hydrogenation in aqueous media. When performed in a single step, using either uniform or staged catalytic bed configuration, high temperature and hydrogen pressures (180°C and 38 bar) are necessary for maximum CPO yields (37 and 49%, respectively). Parallel furanic ring hydrogenation of furfural and polymerisation of intermediates, namely furfuryl alcohol (FFA), limit CPO yields.

Employing a two-step configuration with optimal catalyst bed can curb this limitation. First, the furanic ring hydrogenation can be suppressed by using milder conditions (i.e., 150°C and 7 bar H<sub>2</sub>, and 14 seconds of residence time). Second, FFA hydrogenation using tandem catalysis, i.e., a mix of  $\beta$ -zeolite and Cu/ZrO<sub>2</sub>, at 180°C, 38 bar H<sub>2</sub> and 0.6 gFFA g<sup>-1</sup> cat hr<sup>-1</sup>, allows sufficient time for CPO formation and minimises polymerisation of FFA, thereby resulting in 60% CPO yield. Therefore, this work recommends a split strategy to produce CPO from furfural. Such modularity may aid in addressing flexible market needs.

### Introduction of biogenic carbon into sustainable aviation fuels: applying aldol condensation and selective hydrodeoxygenation technologies to oxygenated bio-intermediates

Dr Ben Smith<sup>1</sup>, Miss Annika Casson<sup>1</sup>, Dr Stefania Scalzullo<sup>2</sup>, Dr Xavier Bauchere<sup>1</sup>, Dr Karla Dussan<sup>3</sup>  
<sup>1</sup>Johnson Matthey, Billingham, United Kingdom; <sup>2</sup>Johnson Matthey, Reading, United Kingdom; <sup>3</sup>Netherlands Organisation for Applied Scientific Research – TNO, Petten, Netherlands.

**HIGFLY – developing sustainable aviation fuels**

Within the fuel sector, aviation is the fastest growing greenhouse-gas emission source and most difficult to decarbonise.<sup>1</sup> Alternative technologies and feedstocks are essential to meet global demand whilst achieving 2050 fly net zero targets,<sup>2</sup> with chemo-catalytic routes considered attractive given their potentially high carbon yield.

The aim of the H2020 HIGFLY<sup>2</sup> project is to develop sustainable aviation fuel (SAF), from second generation feedstock, which mitigates the environmental impact of aviation.

**Aldol condensation of bio-derived feedstock**

Furfural, derived from C5 sugars, has undergone catalytic conversion through aldol condensation reactions with bio-derived ketones to produce oxygenated condensate compounds of increased carbon number. A series of catalysts were investigated based on the conversion of furfural and acetone and furfural and cyclopentanone to the desired double-condensate. Metal-doped alumina, MOF-808 and hydroxalite catalysts were found to be the most active and selective.

**Hydrodeoxygenation of model condensate compounds**

Model condensate products undergo a hydrodeoxygenation (HDO) treatment, which can utilise renewable hydrogen, to yield compounds that can be used as drop-in SAF. Using furfural-acetone single-condensate as a model compound, HDO catalysts investigated have included both nickel-based and PGM-based materials, with the most-active material achieving >98% deoxygenation and >90% Carbon yield, producing SAF molecules of both linear and cyclic nature.

**SAF product composed of Linear and cyclic molecules**

Overall a SAF product has been demonstrated through catalytic aldol condensation of bio-derived feedstock followed by hydrodeoxygenation to yield linear and cyclic molecules in high yields. Cyclic molecules could add value to SAF blends since they may have the potential to swell the seals found in the fuel systems of aviation aircraft.

### Synthesis of jet fuel hydrocarbons using furfural and bio-oxygenates

Karla Dussan<sup>1</sup>, Martin Peters<sup>2</sup>, Stefania M. Scalzullo<sup>2</sup>, Ben Smith<sup>3</sup>, André van Zomeren<sup>1</sup>, Xavier Bauchere<sup>1</sup>, Axel Kraft<sup>2</sup>, Jaap W. van Halbeek<sup>1</sup>  
<sup>1</sup>Netherlands Organisation for Applied Scientific Research – TNO, Petten, Netherlands; <sup>2</sup>Fraunhofer UMSICHT, Oberhausen, Germany; <sup>3</sup>Johnson Matthey, Reading, UK

**HIGFLY concept**

European SAF demand is estimated to be 28 million tonnes by 2050 compared to the current 0.2 million tonnes of SAF produced today<sup>1</sup>. The H2020 HIGFLY project therefore aims to develop the next generation of technologies for the production of sustainable aviation fuels from abundant and sustainable biomass feedstocks or second generation (2G) biomass. HIGFLY develops a combination of technologies that produces kerosene hydrocarbons via biobased oxygenated precursors derived from 2G carbohydrates.

**Jet fuel production routes**

Furanic molecules have been investigated in aldol-condensation process at lab scale with other (potentially) bio-based molecules<sup>2,3</sup>. The concept is based on two steps: (1) catalytic condensation to intermediate oxygenated condensates and (2) hydrodeoxygenation to saturated hydrocarbons. Two routes are evaluated as part of the H2020 HIGFLY project, where we use (2G sugar-derived) furfural and acetone as cross-condensation agent, and (furfural-derived) cyclopentanone for self-condensation.

**Catalyst performance for Furfural + Acetone condensation**

**Process development**

Our work focused on the development and selection of solid catalysts in particular for the condensation step and on the scalability of the process through testing in fixed bed reactors under continuous operation at lab scale. Commercial and developmental catalysts provided high conversions in the condensation steps<sup>4</sup>; however, catalyst deactivation due to carbon deposition was observed over time. Regeneration through calcination aided to reactivate materials and extend their lifetime.

**Fuel sample after hydrodeoxygenation**

**Preliminary fuel properties & outlook**

The two step processes were integrated to produce representative fuel samples through the HIGFLY concept. Carbon yields to liquid fuel were higher than 88% for the two routes. High fuel product yields are attainable through these routes; however, complete deoxygenation was challenging; the process at lab scale is not directly comparable with optimised processes at industrial scale, where larger and undiluted catalyst beds or series of multiple reactors can be integrated for attaining better heat control and carbon yields. Preliminary characterisation of the fuels indicates that high freezing point and/or the step-wise distillation behaviour may hinder the use of these fuel products in sustainable aviation. However, these issues can be further addressed through further optimisation of the downstream catalytic conversion (e.g. isomerisation) and the use of diverse set of fuel precursors.

Property	ASTM D7568 Specification	Furfural-derived fuel	CPO-derived fuel
Carbon, % wt	-	84.3	86.6

# Converting bio-based cyclopentanone into jet fuel hydrocarbons

OPEN & DOWNLOAD THE POSTER HERE

**Fraunhofer UMSICHT**

**The HIGFLY approach**  
In 2021 the International Air Transportation Agency (IATA) members agreed in a net zero CO<sub>2</sub> emission in 2050. To reach this goal the global production capacities of 300 million litres SAF in 2022 must be increased drastically. A potential production of 30 billion litres is a scenario for 2030.<sup>1</sup> In this context the H2020 project HIGFLY develops novel technologies and processes to contribute to the increasing demand on SAF. The starting point for the HIGFLY approach are sustainable feedstocks and second-generation biomasses which are processed to bio-based oxygenates like cyclopentanone. These precursors were condensed to larger molecules and subsequently hydrodeoxygenated to pure jet fuel hydrocarbons.

**Liquid products from CPO self-condensation**

**Spent catalysts from condensation**

**Gas phase condensation**  
Fraunhofer UMSICHT investigated a high-temperature gas phase condensation for the synthesis of jet fuel precursors. Typical reaction parameters are 320 to 360 °C and a WHSV of 6 mmol g<sup>-1</sup> h<sup>-1</sup>. Different commercial and scientific catalysts have been tested for their performance and stability. Finally, a novel basic catalyst developed by Johnson Matthey was chosen for the process development. As expected, the catalyst showed a significant higher CPO conversion at 360 °C compared to the results at 280 °C. Additionally, at 360 °C tricyclic molecules were formed. Each experiment shows a decreasing catalytic activity between 50 and 80 h on stream.

**Conversion and Yields of cyclopentanone condensation**

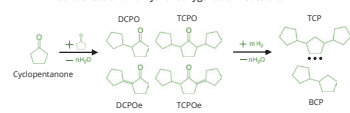

Reaction temperature	Conversion CPO (%)	Yield DCPo (%)	Yield TCPO (%)	Yield TCPOe (%)
280 °C	25.7	23.2	2.6	0.0
360 °C	42.8	33.8	3.0	6.0

**References**  
1. IATA, Annual Review 2023; p. 27-29  
2. Muldoon, J.A.; Harvey B.G., ChemSusChem, 2020, 13(22): p. 5777-5807

**Converting bio-based cyclopentanone into jet fuel hydrocarbons**

Martin Peters<sup>1</sup>, Karla Dussan<sup>2</sup>, Stefania M. Scalluzzo<sup>1</sup>, Ben Smith<sup>1</sup>, André van Zomerem<sup>1</sup>, Xavier Baücherer<sup>2</sup>, Axel Kraft<sup>1</sup>, Jaap W. van Halbeek<sup>1</sup>  
<sup>1</sup> Fraunhofer UMSICHT, Oberhausen, Germany; <sup>2</sup> Netherlands Organisation for Applied Scientific Research - TNO, Petten, Netherlands; <sup>3</sup> Johnson Matthey, Reading, UK

**Condensation and Hydrodeoxygenation reactions**

**Continuous hydrodeoxygenation**  
The bicyclic C10 and tricyclic C15 jet fuel intermediates were hydrodeoxygenated in a bench-scale plant. To obtain relevant results regarding future large-scale application the plant was revamped with a gas recycle to analyse accumulation of side products i.e. from cracking. The intermediates were hydrodeoxygenated three times at identical conditions which are 270 °C reaction temperature, a WHSV of 10 h<sup>-1</sup> and 50 bar reaction pressure. The hydrogen excess compared to the stoichiometric demand was 4. The conversion of the intermediates increases to 100 % after the third HDO, while an overall BCP yield of 95.8 % was reached.

**Conversions and Yield of bicyclic molecules during HDO runs**

Number of Hydrodeoxygenation	Conversion DCPo (%)	Conversion TCPO (%)	Yield BCP (%)
1st HDO	93.0	27.3	-
2nd HDO	100.0	88.5	74.5
3rd HDO	100.0	100.0	95.8

**Discussion & outlook**  
The condensation of cyclopentanone and the subsequent hydrodeoxygenation of the jet fuel intermediates are a promising pathway to cyclic jet fuel components. Especially cyclic non-aromatic compounds are seen as key components for the performance of jet fuel. They are valuable blend components for bio-based fuels. For example, the freezing point of BCP is -38 °C and therefore significantly lower than the freezing point of linear hydrocarbons.<sup>2</sup> For the synthesis of bi and tricyclic hydrocarbons from cyclopentanone a two-step process has been developed in lab scale. The hydrodeoxygenation was operated stable but the condensation reaction shows a fast catalytic deactivation. The deactivation was addressed by intermediate regeneration. Nevertheless, more research is needed for a large-scale process design.

In 2021 the International Air Transportation Agency (IATA) members agreed to a net zero CO<sub>2</sub> emissions target by 2050. To reach this goal the global production capacities of 300 million litres SAF in 2022 must be increased drastically. A potential production of 30 billion litres is a scenario for 2030. In this context the H2020 project HIGFLY develops novel technologies and processes to contribute to the increasing demand on SAF. The starting point for the HIGFLY approach are sustainable feedstocks and second-generation biomasses which are processed to bio-based oxygenates like cyclopentanone. These precursors were condensed to larger molecules and subsequently hydro-deoxygenated to pure jet fuel hydrocarbons.

# Assessment of Bio-Advanced Synthetic Aviation Fuel Hydrocarbons Production from Biorefinery Streams using Furfural and Ketones: A Techno-Economic Analysis

Biomass plays a crucial role in reducing greenhouse gas emissions within the aviation industry. The European Commission, through the REfuelEU aviation initiative as part of the Fit for 55 package, acknowledges this and encourages investments in cleaner technologies for sustainable aviation fuels. In this context, the HIGFLY project aims to develop advanced bio-jet fuels by converting underutilised hemicellulose (C5) fractions into hydrocarbons suitable for blending with jet fuel. <sup>1</sup> The Netherlands Organisation for Applied Scientific Research TNO, Petten, the Netherlands

**Introduction**  
Biomass plays a crucial role in reducing greenhouse gas emissions within the aviation industry. The European Commission, through the REfuelEU aviation initiative as part of the Fit for 55 package, acknowledges this and encourages investments in cleaner technologies for sustainable aviation fuels. In this context, the HIGFLY project aims to develop advanced bio-jet fuels by converting underutilized hemicellulose (C5) fractions into hydrocarbons suitable for blending with jet fuel. Supporting experimental work, the current work presents process design for different technological pathways and evaluating the technical and economic aspects for long-term sustainability and commercialization of these sustainable aviation fuels.

**Method**

**Process alternatives**  
Within the HIGFLY project, three main process alternatives were investigated to obtain bio-based SAF components derived from C5 sugars through intermediates furfural (A), furfural-cyclopentanone (B), and cyclopentanone (C).

**Starting points**

- Conversions based on current status of technology development based on experimental results
- C5 sugars: biorefinery by-product (202 EUR/tonne)
- Import green hydrogen (2500 EUR/tonne)
- Revenues for side products (alkanes <C9) (1.5 EUR/l)

**Key results and outlook**

**Scenario A (Furfural-derived):**

- Relies on import precursor, acetone
- High carbon efficiency (67%)
- Lowest heat demand

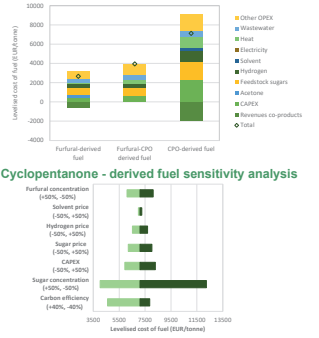

**Scenario B (Furfural-Cyclopentanone (CPO) derived):**

- More complex process (involving an additional step)
- Lower carbon efficiency (49%) due to low CPO yields
- Sub-optimal heat demand: water-based process with low concentrations

**Scenario C (Cyclopentanone (CPO)-derived):**

- Highest complexity process
- Lowest carbon efficiency (38%) due to poor CPO yields
- Highest heat demand: water-based process with low concentrations and full conversion of furfural to CPO

**Cyclopentanone - derived fuel sensitivity analysis**

**Outlook**  
Currently, Scenario A appears to be the most economically attractive option, requiring acetone import. Scenarios B and C may hold promise for the future if improved carbon efficiency and higher furfural concentrations in the feed can be achieved through further technology development.

# RELATED PROJECTS

The **TAKE-OFF** project, funded under the European Union's Horizon 2020 research and innovation program, is focused on developing advanced technologies to produce next-generation **Sustainable Aviation Fuel (SAF)**. This project employs an innovative process that captures **CO<sub>2</sub>** from industrial flue gases or directly from the air, combines it with **renewable hydrogen**, and converts

it into light olefins—chemical intermediates that are subsequently upgraded into SAF. This method offers significant advantages in terms of energy efficiency and cost compared to existing power-to-liquid alternatives.

TAKE-OFF aims to significantly reduce the carbon footprint of aviation by replacing conventional fossil-based jet fuels with synthetic SAF. The project is expected to achieve a **25% improvement in carbon and hydrogen efficiency**, a **36% reduction in production costs**, and a **20% reduction in total emissions** compared to current alternatives. Additionally, it elimina-

tes sulphur emissions entirely, aligning closely with European Green Deal targets and the Renewable Energy Directive II objectives.

The project also focuses on demonstrating the economic and environmental viability of its technology through pilot-scale implementation and comprehensive life-cycle assessments. By advancing the production technologies from Technology Readiness Levels (TRLs) 3 to 5, TAKE-OFF supports the broader adoption of SAF within the aviation industry.
